Design

In the context of software development, coupling refers to the level of reliance between two software application modules, classes, or objects. When there are several interdependencies between two modules, this is known as tight coupling. In contrast, loose coupling refers to situations when there are few relationships between two modules.

What technologies exist for language coupling?

SWIG-

A software development tool called SWIG links C and C++ programs with a number of high-level programming languages. SWIG is generally used to parse C/C++ interfaces and generate the 'glue code' required for the above target languages to call into the C/C++ code.

Pybind11-

It is a lightweight header-only library that presents C++ types in Python and vice-versa, primarily to enable the creation of Python bindings for C++ code that already exists. It has similar objectives and syntax as the famous Boost.Library for Python.

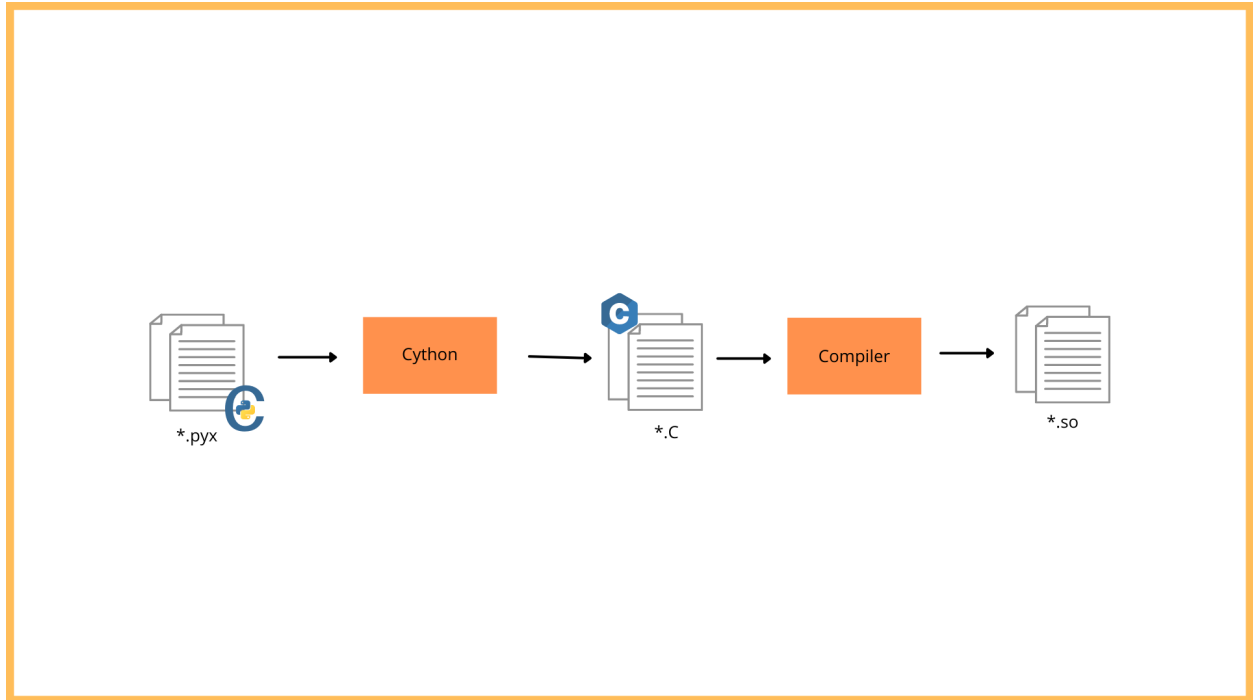

- Have a c++ code and port to python.
- Want to move object oriented code in python to c++ for performance.

- Want to synchronize backend code between python and c++

Cython -

The Cython language is a superset of Python. Cython compiles the python code to c, thus increasing the performance of the code for several magnitudes. The speedups won't be significant while using native object types in Python. However, the gains can be substantial for operations using numbers or any actions not involving Python's own internals. Without having to give up Python's simplicity and convenience, Cython allows you to get around or even go around all of its native limitations.

Architecture

What modern language couplings exist? Lua? Python?

A versatile technique exists in Lua for binding to programs created in other languages. Functions in libraries written in C can be made accessible to your Lua programs through the C application Programming interface. languages like C++ and Pascal are compatible with the C calling convention — these languages work fine with Lua. For python, the above section already presented the technologies useful for coupling.

How is it done?

We want to present how Cython works for the python code with C/C++. Python with C data types is basically Cython. Any cython code is valid in python code. But in cython we can declared c variables which can increase performance.

- A filename.pyx is created
- A setup.py file is created.

```
from setuptools import setup
from Cython.Build import cythonize
```

```
setup(
    ext_modules = cythonize(" filename .pyx")
)
```

- Now run which builds the cython file. The .pyx file is compiled by cython which gives a .c file.

```
$ python setup.py build_ext --inplace
```

- A .c file is created and compiled by c which produces .so file.
- Now import this file simply by writing import to that .so file to our actual code.

```
Import filename
```

- Thus data types in c can be used in python for faster performance.

In this lab, we have used cython for coupling languages C/C++ and python.

- Pip Install cython
- Build main.pyx which has generic python function(prime numbers) by defining data types using c language data types.
- Create a setup.py which translates main.pyx file into c/c++ optimized code which generates main.c. this helps in faster execution of the code and also binds the c libraries. Cython compiles .pyx file to .c which contains the python module.
- C compiler compiles the .c file which produces the .so file. This is taken care of by setup.py which has setuptools.
- Imported the module into newly created test.py and call the functions we created.

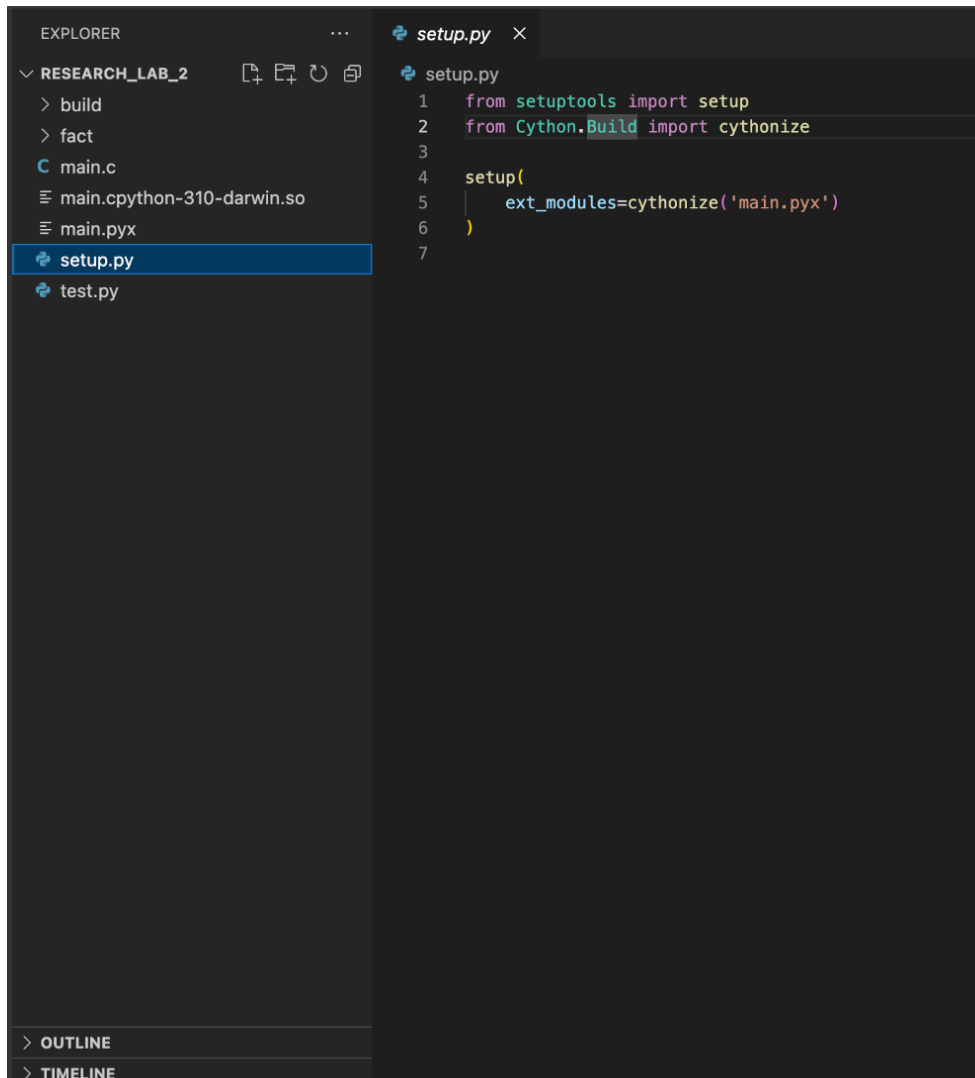

1. Create a main.pyx file

```
EXPLORER
...
RESEARCH_LAB_2
  > build
  > fact
  C main.c
  main.cpython-310-darwin.so
  main.pyx
  setup.py
  test.py

> OUTLINE
> TIMELINE
0

main.pyx
1 def get_prime_numbers_py(amount):
2     prime_nums = []
3
4     found = 0
5     num = 2
6
7     while found < amount:
8         for x in prime_nums:
9             if num % x == 0:
10                 break
11             else:
12                 prime_nums.append(num)
13                 found += 1
14             num += 1
15     return prime_nums
16
17
18 def get_prime_numbers_cy(int amount):
19     cdef int num, x, found
20     cdef int prime_nums[1000000]
21
22     amount = min(amount, 1000000)
23
24     found = 0
25     num = 2
26
27     while found < amount:
28         for x in prime_nums[:found]:
29             if num % x == 0:
30                 break
31             else:
32                 prime_nums[found] = num
33                 found += 1
34             num += 1
35
36     return_list = [p for p in prime_nums[:found]]
37
38     return return_list
39
```

2. Create a setup.py file where we have setuptools which gives platform related compilation options and cythonize which helps the .pyx file in compiling the code to C/C++ .

The screenshot shows a code editor with a dark theme. On the left, the 'EXPLORER' sidebar displays a file tree for a project named 'RESEARCH_LAB_2'. The files listed are 'build', 'fact', 'main.c', 'main.cpython-310-darwin.so', 'main.pyx', 'setup.py' (which is selected and highlighted in blue), and 'test.py'. At the bottom of the sidebar, there are sections for 'OUTLINE' and 'TIMELINE'. The main editor area on the right shows the content of 'setup.py'. The code is as follows:

```
1 from setuptools import setup
2 from Cython.Build import cythonize
3
4 setup(
5     ext_modules=cythonize('main.pyx')
6 )
7
```

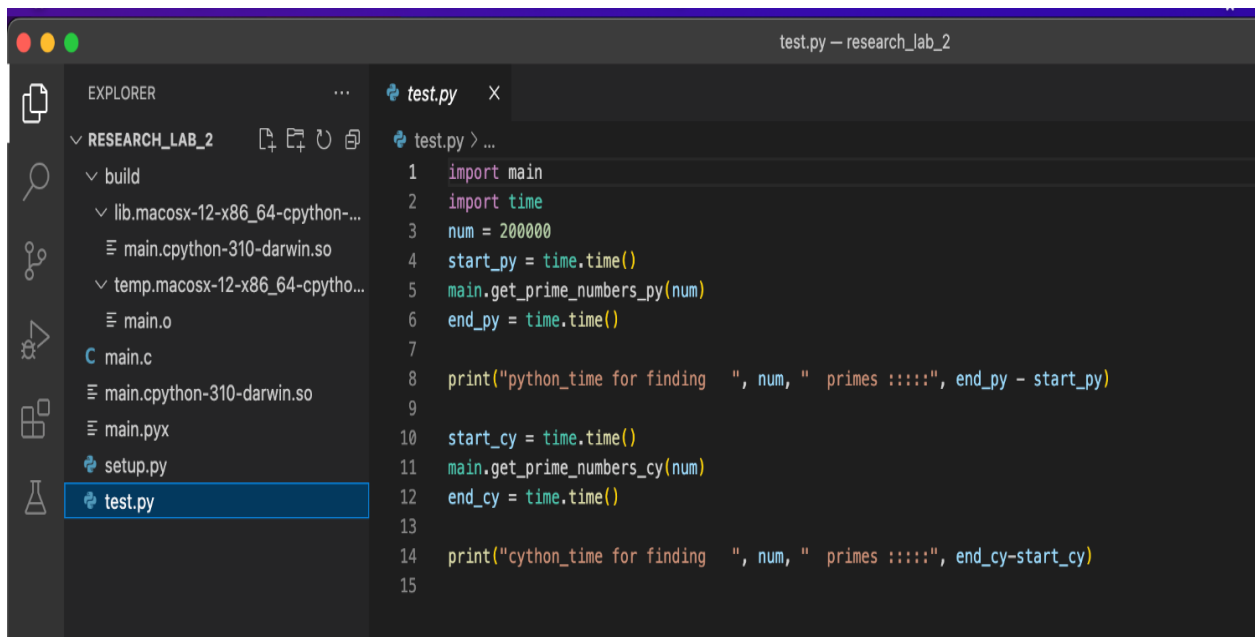

3. Run `$ python setup.py build_ext --inplace`
4. A .c file is generated and the c compiler compiles that .c file.
A build directory which contains .o file is generated by the compiler. And a .so file which is a compiled library file.

```
main.c -- research_lab_2

C main.c
C main.c
1207 /* CheckBinaryVersion.proto */
1208 static int __Pyx_check_binary_version(void);
1209
1210 /* InitStrings.proto */
1211 static int __Pyx_InitStrings(__Pyx_StringTabEntry *t);
1212
1213
1214 /* Module declarations from 'main' */
1215 #define __Pyx_MODULE_NAME "main"
1216 extern int __pyx_module_is_main_main;
1217 int __pyx_module_is_main_main = 0;
1218
1219 /* Implementation of 'main' */
1220 static const char __pyx_k_p[] = "p";
1221 static const char __pyx_k_x[] = "x";
1222 static const char __pyx_k_num[] = "num";
1223 static const char __pyx_k_main[] = "_main_";
1224 static const char __pyx_k_name[] = "_name_";

1242 static PyObject *__pyx_kp_s_main_pyx;
1243 static PyObject *__pyx_n_s_name;
1244 static PyObject *__pyx_n_s_num;
1245 static PyObject *__pyx_n_s_p;
1246 static PyObject *__pyx_n_s_prime_nums;
```

```
setup.py
setup.py
1 from setuptools import setup
2 from Cython.Build import cythonize
3
4 setup(
5     ext_modules=cythonize('main.pyx')
6 )
7
```

5. Import the Cython file just like the python module.

```
test.py -- research_lab_2

EXPLORER
  RESEARCH_LAB_2
    build
    lib.macosx-12-x86_64-cpython-...
      main.cpython-310-darwin.so
    temp.macosx-12-x86_64-cpytho...
      main.o
    main.c
    main.cpython-310-darwin.so
    main.pyx
    setup.py
    test.py

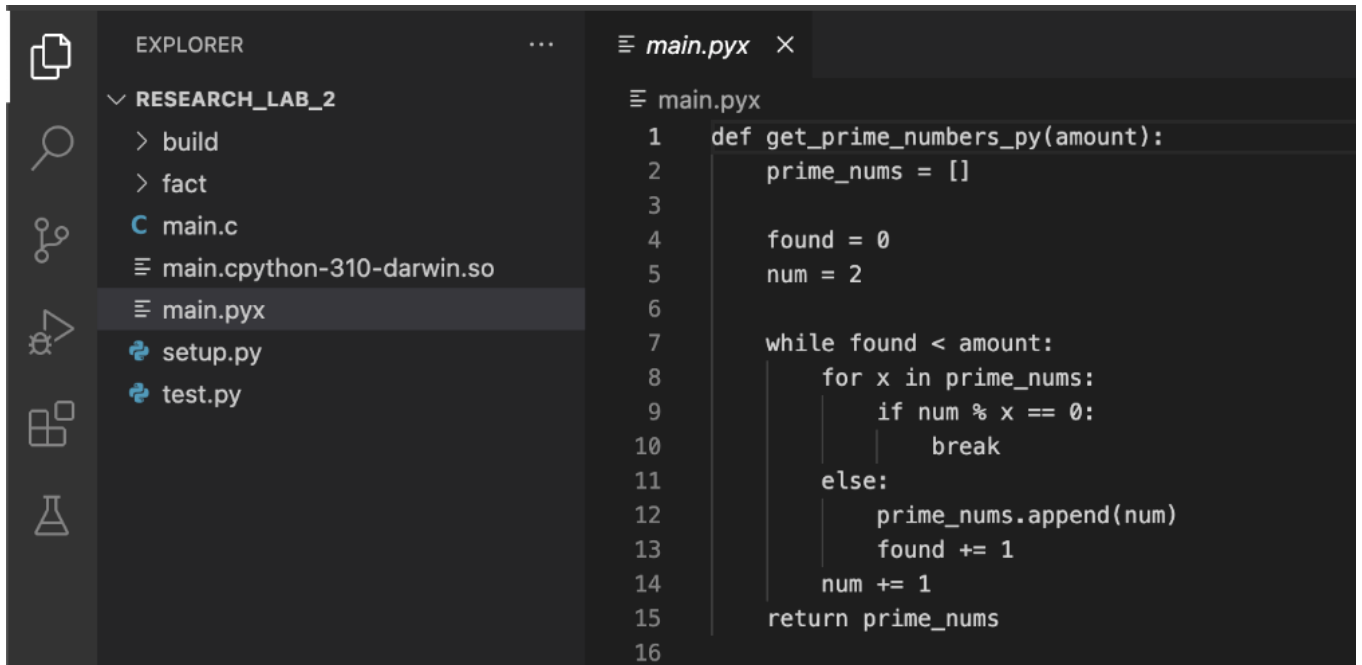

test.py
1  import main
2  import time
3  num = 200000
4  start_py = time.time()
5  main.get_prime_numbers_py(num)
6  end_py = time.time()
7
8  print("python_time for finding ", num, " primes ::::", end_py - start_py)
9
10 start_cy = time.time()
11 main.get_prime_numbers_cy(num)
12 end_cy = time.time()
13
14 print("cython_time for finding ", num, " primes ::::", end_cy-start_cy)
15
```

6. Now run the python file.

Results

We have written both pure python and cython codes in the main.pyx file inorder to compare the results for both code performances.

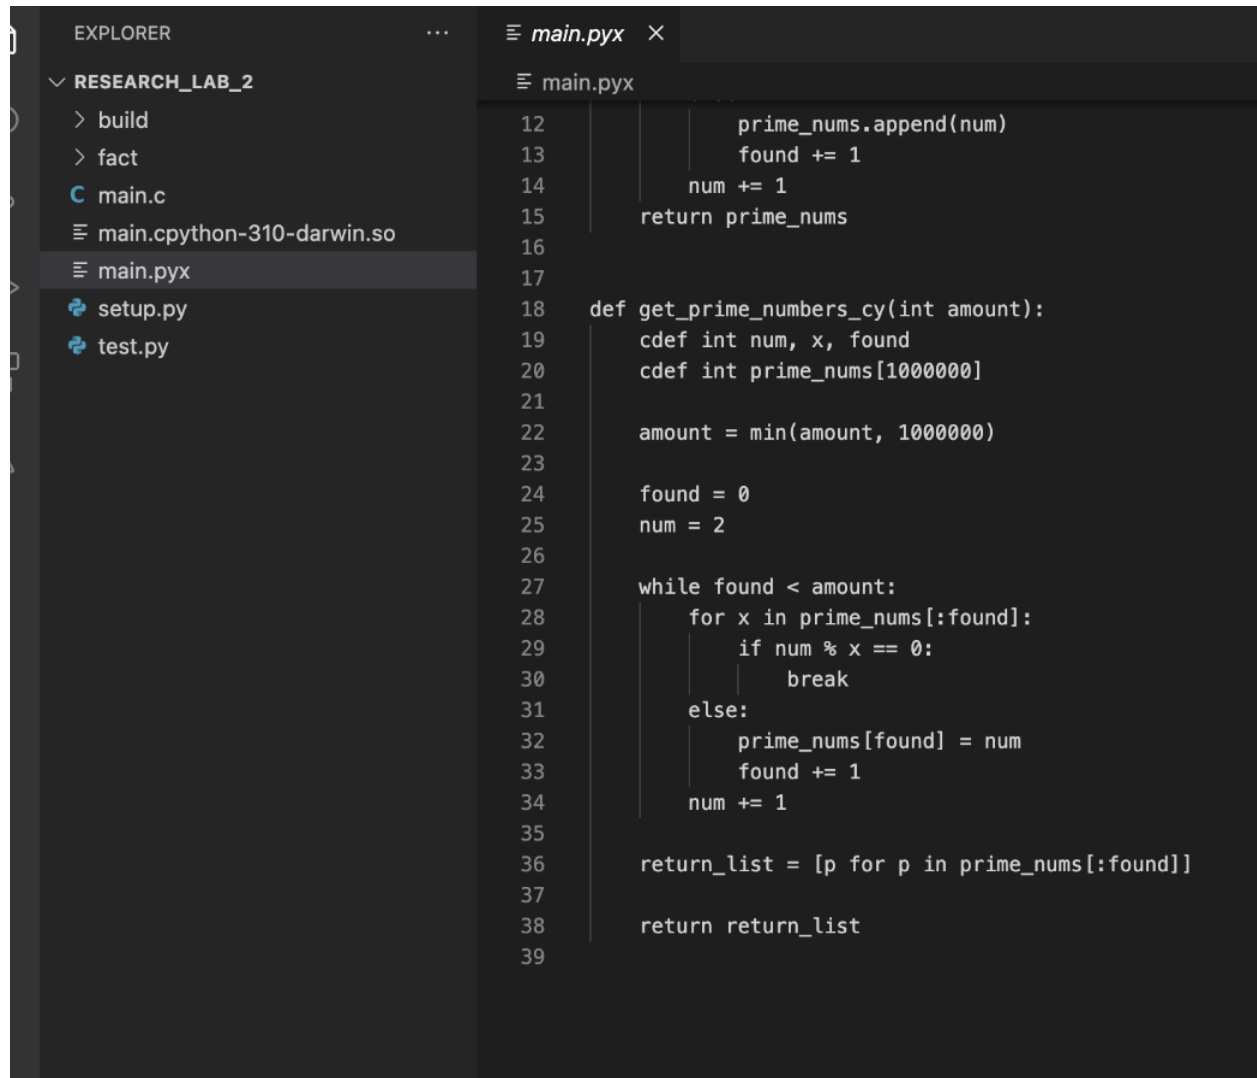

Pure python code -

```
EXPLORER
RESEARCH_LAB_2
  build
  fact
  main.c
  main.cpython-310-darwin.so
  main.pyx
  setup.py
  test.py

main.pyx
1  def get_prime_numbers_py(amount):
2      prime_nums = []
3
4      found = 0
5      num = 2
6
7      while found < amount:
8          for x in prime_nums:
9              if num % x == 0:
10                 break
11             else:
12                 prime_nums.append(num)
13                 found += 1
14                 num += 1
15         return prime_nums
16
```

Cython code-

The image shows a code editor interface with a dark theme. On the left is the 'EXPLORER' sidebar showing a project named 'RESEARCH_LAB_2'. It contains several files: 'build', 'fact', 'main.c', 'main.cpython-310-darwin.so', 'main.pyx' (which is selected), 'setup.py', and 'test.py'. The main editor area displays the code for 'main.pyx'. The code is a CPython extension module that implements a function to find prime numbers. It uses Cython syntax, with 'cdef' for C variables and 'def' for Python functions. The code includes a list 'prime_nums' to store found primes and a 'while' loop that iterates through numbers, checking for divisibility. The function 'get_prime_numbers_cy' returns a list of primes up to a specified amount.

```
12         prime_nums.append(num)
13         found += 1
14         num += 1
15     return prime_nums
16
17
18 def get_prime_numbers_cy(int amount):
19     cdef int num, x, found
20     cdef int prime_nums[1000000]
21
22     amount = min(amount, 1000000)
23
24     found = 0
25     num = 2
26
27     while found < amount:
28         for x in prime_nums[:found]:
29             if num % x == 0:
30                 break
31         else:
32             prime_nums[found] = num
33             found += 1
34             num += 1
35
36     return_list = [p for p in prime_nums[:found]]
37
38     return return_list
39
```

Output-

```

koushik@USCS-Mac123 research_lab_2 % python3 test.py
python_time for finding 1 primes :::: 9.5367431640625e-07

cython_time for finding 100000 primes :::: 16.276087999343872

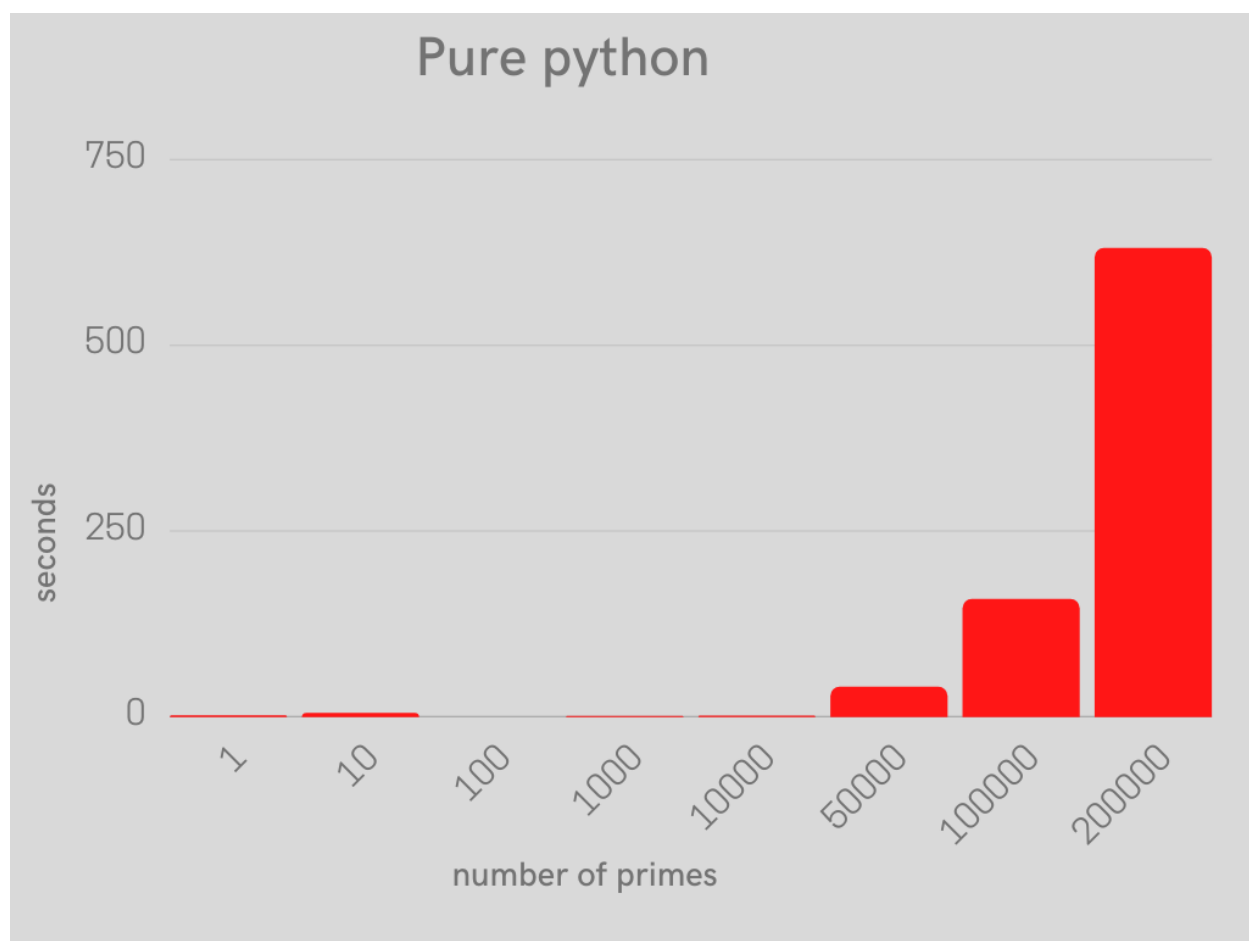

```

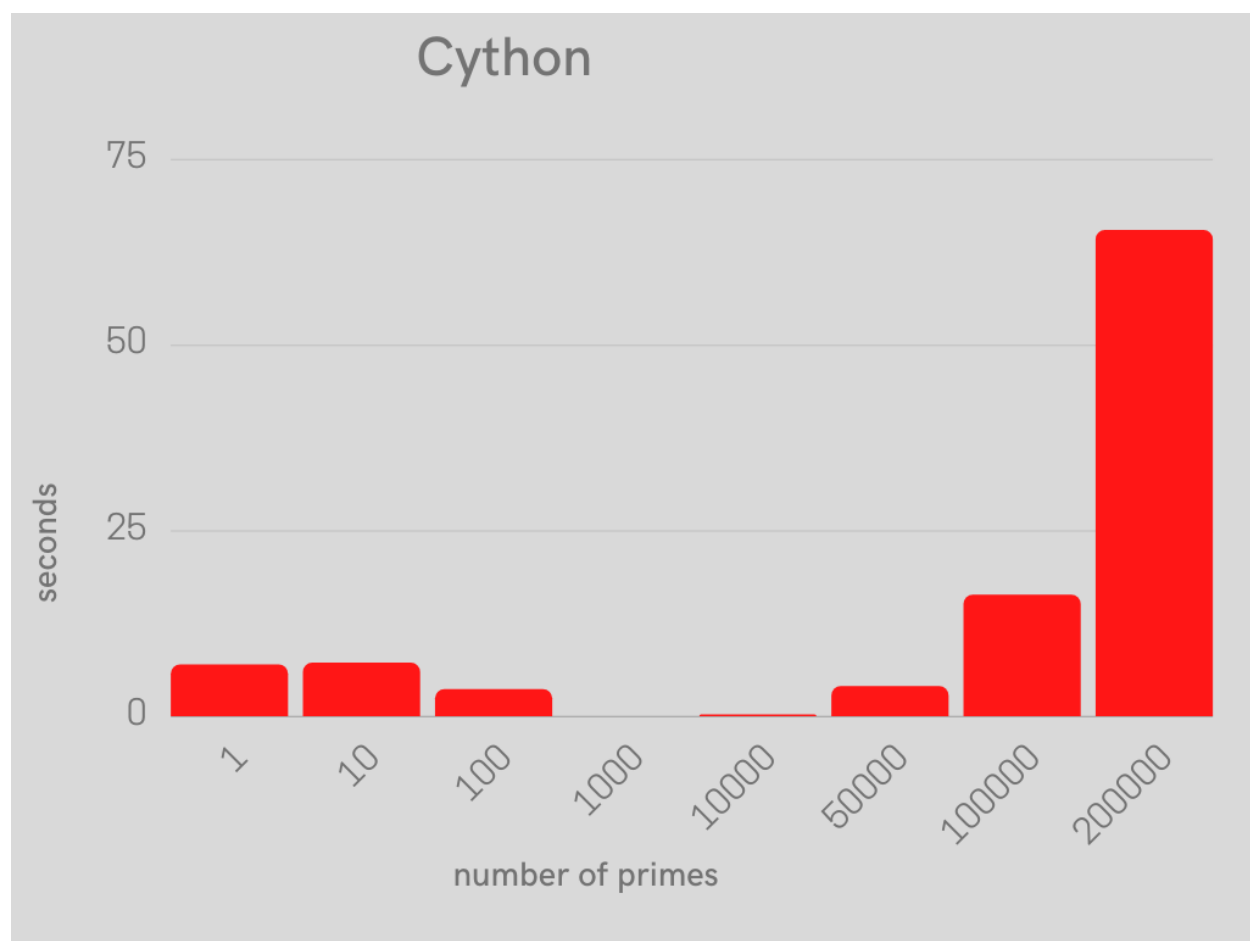

At first python code performance is better when compared to cython code. But eventually, when the number of for loops increased, the performance for the cython code was increased as it utilized cdef to declare variables in cython for c data types.
